

VIT Vidyashankar Institute of Technology Accredited A+ by NAAC (Autonomous College Affiliated to University of Mumbai)		End Semester Examination (CBCGS-C scheme) -(2022-23)		
Date: 17 Nov 2022	Branch: Computer Engineering	Time: 2 Hr.		
Semester: VII	Subject: Big Data Analytics	Marks: 50		
N.B.: All Questions are Compulsory		CO	BL	
Q.1) Attempt any Five (2 Marks Each)				
a) What is CAP theorem?	CO3	L1		
b) Explain any 2 characteristics of NoSQL database.	CO3	L2		
c) What is Sliding window sampling technique for big data.	CO4	L1		
d) List components of DSMS (Data Stream Management System) architecture.	CO4	L2		
e) Give any 4 examples of social network graph	CO5	L2		
f) Define social network and Social Network mining.	CO5	L1		
g) List any 2 basic features of R	CO6	L2		
h) Explain any 2 functions that allow users to handle data in R.	CO6	L1		
Q.2) Attempt any two. (5 Marks Each)				
a) Compare NoSQL database with RDBMS.	CO3	L1		
b) Explain Key-Value store architecture pattern with example.	CO3	L2		
c) Explain Column family store architecture pattern.	CO3	L2		
Q 3) Attempt any One (10 Marks Each)				
a) How bloom filter is useful for big data analytics? Explain with one example	CO4	L3		
b) Explain Flajolet-Martin (FM) algorithm. Using FM algorithm, compute number of distinct elements in the set $S=\{1,3,2,1,2,3,4,3,1,2,3,1\}$ with hash function $h(x)=(6x+1) \bmod 5$.	CO4	L2		
Q 4) Attempt any One (10 Marks Each)				
a) Compare Content based filtering and Collaborative filtering in Recommendation System.	CO5	L4		
b) Explain the Detect communities in the below given social graph using Girvan-Newman (GN) algorithm	CO5	L3		
Q 5) Attempt any One. (10 Marks Each)				
a) What are the different data structures in R. Explain with example.	CO6	L1		
b) List and discuss different types of data visualizations techniques.	CO6	L1

	1	
	a)	In theoretical computer science, the CAP theorem states that any distributed database system can only provide 2 of the following 3: i) Consistency ii) Availability iii) Partition tolerance. In other words, if a network of distributed system database system fails then it can either provide Consistency or Availability and not both.
	b)	2 characteristics of NoSQL: i) Volume :- NoSQL databases are highly scalable which makes them suitable for large amount of data. ii) Variability :- NoSQL databases accommodate heterogeneous data. They do not require data in any structure and hence are flexible in terms of their usage and reliability. c) In sliding window sampling technique, a window of specified length moves over the data. Statistical analysis is performed over this window. This window captures recent N entries of data and is used by

		several algorithms like DGRIM to detect number of 1's in the window.
	d)	Components of DSMS are.
		1) Input stream data 2) Working storage 3) Archive storage 4) Query processor 5) Repository of Standing queries. 6) Output Buffer. 7) SLP stream of data.
	e)	Examples of social network graph are
		i) Facebook friend graph ii) Twitter follower graph. iii) LinkedIn contact graph iv) Publication co-author graph. v) WhatsApp contact graph. etc..
	f)	Social Network is a dedicated platform (website or application) which enables users to have social interactions with each other through posts, messages, comments, reactions, images, etc... Social network mining is the process of obtaining information from user-generated big data on social media platforms.

	g)	R has many features such as: i) It is open source ii) It has powerful graphics iii) It has effective data handling & storage facilities. iv) It can perform complex statistical calculations on big data. etc..
	h)	R has facility to read different types of files. Functions available include: i) read.table () : To read text files ii) read.csv () : To import from CSV file iii) read.xls () : ——— xls file. etc.. It also supports directory operations like. (i) getwd () (ii) setwd ()
		And to read list files of directory it has list.files () function.

	2		
(a)	No SQL	RDBMS	
	1) Designed to handle large volume of data	Designed to handle moderate volume of data	
	2) It handles all types of data (structured, semi-structured and un-structured)	It is designed to handle only structured data (set of relations) only	
	3) It is designed to support analytical operations & simple transactions	It is designed to support complex transactions & perform simple analysis.	
	4) It supports BASE property	It supports ACID property.	
	5) It is designed to handle data coming from many sources and at high velocity	It is designed to handle data from one or few sources and at low velocity.	
	6) Does not support changes in database	Supports frequent updates to database	
	7) Ex: Amazon Dynamo, MongoDB.	Ex: Oracle 8i, PostgreSQL.

2	b)	<p>The key-value store is the most simple and an No SQL architecture pattern. In this model, a simple string or a collection of values or a complex entity are all treated as values. These values are identified by a single key such that each key uniquely identifies its value. Although same key can associate to a set of values.</p> <p>Databases designed on key-value store pattern, use an efficient and compact indexing or hashing structure for the key. This enables rapid search of values associated with the key.</p>  <p>such as</p>

Space for Marks	Question No.	START WRITING HERE
		Advantages of Key-value stores <ul style="list-style-type: none"> → Easy to use. due to simplicity → Efficient (quick response time) → Scalable (handles large volume) → Reliable
		Drawbacks of Key-value store <ul style="list-style-type: none"> → Cannot retrieve values without key. → No query language support.
		Examples: Amazon DynamoDB, Berkeley DB, Couchbase etc..
2 c)		Column family store architecture pattern can be seen as a flipped version of relational databases wherein each column of rows is treated as a separate row of column store. A column need not always be associated with a set of values, it can also have a group of columns within it. These are known as column family such as <pre> graph TD Employee[Employee] --> Personal[Personal] Employee --> Experience[Experience] Employee --> Record[Record] Employee --> Design[Design] Personal --> Name["Name"] Personal --> DOB["DOB"] Personal --> Gender["Gender"] Personal --> Record Experience --> Record Record --> Record Design --> Record </pre> <p>The diagram illustrates the column family store architecture. It starts with a box labeled "Employee". Four arrows point from "Employee" to four separate boxes: "Personal", "Experience", "Record", and "Design". From the "Personal" box, four arrows point to sub-boxes: "Name", "DOB", "Gender", and "Record". The "Experience" and "Record" boxes also have arrows pointing to their own "Record" sub-boxes. The "Design" box has an arrow pointing to its own "Record" sub-box.</p>

		Every column is treated separately. Every column format can vary from one row to another.
		<u>Advantages:</u> → Data is readily available. → Easier to perform aggregate operations on column such as sum, AVG, -
		<u>Drawbacks:</u> → Designing effective working schema is difficult. → Although similar to relational model, this model is less reliable secured and not suitable for transaction processing
		<u>Examples</u> HBase Bigtable by Google Cassandra etc - -

	<u>3q</u>	<p>Bloom filter is used to check whether an element is a member of a set or not. It also uses hash search technique. Instead of using regular hash search technique, Bloom filter uses a space-efficient model where in for each hash position it stores a 0 or a 1.</p> <p>0 → No element hashed to the location. 1 → An element has hashed to the location.</p> <p>To reduce number of false positives (caused due to collision) it uses multiple hash functions. Number of hash functions to use depends on the probabilistic analysis of Bloom filter.</p> <p>An element x_i is said to be present if for every hash function there is a 1 then the element x_i is considered to be a member of set S, else not a member.</p> <p><u>Example</u>: Consider Set $S = \{3, 5, 8\}$ and hash functions</p> <p>$h_1(x) \equiv x * 7 \pmod{13}$ $h_2(x) \equiv x * 3 \pmod{13}$ $h_3(x) \equiv x * 9 \pmod{13}$</p>

Space for Marks	Question No.	START WRITING HERE																										
		<p>Initial Bit Vector</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <tr> <td>0</td><td>1</td><td>2</td><td>3</td><td>4</td><td>5</td><td>6</td><td>7</td><td>8</td><td>9</td><td>10</td><td>11</td><td>12</td> </tr> <tr> <td>0</td><td>0</td><td>1</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td> </tr> </table>	0	1	2	3	4	5	6	7	8	9	10	11	12	0	0	1	0	0	0	0	0	0	0	0	0	0
0	1	2	3	4	5	6	7	8	9	10	11	12																
0	0	1	0	0	0	0	0	0	0	0	0	0																

Element 3

$$h_1 = (3 * 7) \bmod 13 = 8$$

$$h_2 = (3 * 3) \bmod 13 = 9$$

$$h_3 = (3 * 5) \bmod 13 = 2$$

Hence Bit vector become

0	1	2	3	4	5	6	7	8	9	10	11	12
0	0	1	0	1	0	1	0	1	1	0	1	0

Similarly, for element 5 4 8

$$h_1 = (5 \times 7) \bmod 13 = 9 \quad (8 \times 7) \bmod 13 = 4$$

$$h_2 = (5 * 3) \bmod 13 = 2 \quad (8 * 3) \bmod 13 = 11$$

$$h_2 = (5 * 5) \bmod 13 = 2 \quad (8 * 5) \bmod 13 = 1$$

Q. Bit vector after all element inserted

0	1	2	3	4	5	6	7	8	9	10	11	12
0	1	1	0	1	0	0	0	1	1	0	1	0

Now consider an element 4

$$h_1 \text{ gives } (4+7) \bmod 13 = 8 \quad (\text{if } \oplus \text{ is +})$$

h_2 gives $(4 \times 3) \bmod 13 = 12$ (it's 0)

Therefore 4 is not present in the set.

		Next, FM algorithm determines the max of σ as R . For above example $R = \max\{0, 1, 2\} = 2$
		Hence, number of distinct elements as per FM algorithm are 2^R
		For the given example, Number of distinct elements = $2^2 = 4$
		<u>Q9</u> Comparison between Content & Collaborative Filtering for recommendation systems.
	i)	Content based filtering has lots of information about item features. Such as, for a movie, its genre, release year, director, actor, etc. Whereas, Collaborative based filtering does not rely on items features. It is based on similarity between two users.
	ii)	Content based filtering groups items based on their similar features & user history of user to create item profile for user. Whereas, collaborative filtering groups users having similar interest and recommends items based on rating by other members of the group.
	iii)	Content based filtering can recommend

		a new item to user because it matches the item profile interest of the user.
		Whereas, collaborative filtering has difficulty in recommending a new item to any user unless it is liked by others in group.
	iv)	Content based filtering can create profile for new user by explicitly asking questions relevant to create user's profile. Whereas, collaborative filtering cannot create recommend items to new user, unless there is a history
	v)	Content based recommends similar items also user and hence gets over specified at times. Whereas, Collaborative based recommends items with varied features and can cater to multiple interests of a user group.

Example: Consider a case of movie recommendation.

Content based: will recommend movies to a user ~~to~~ only based on the user's history & movie's feature. Thereby, it can cater to multiple users but can get over specialized.

Collaborative based: will create group of users who like similar movies and if a user from group likes a movie, it will recommend that movie to all others in group.

1b		Girvan - Newman algorithm for Community detection.
		Approach of GN algorithm is to determine edge betweenness for all edges of a community graph and (connected graph) and remove the edge having highest edge betweenness. This leads to creating 2 or more communities of of the graph.
		The above procedure is repeated for each community till the threshold is met.
		It is based on Hierarchical decomposition technique of clustering.
		Steps of GN are as follows -
		i) Consider any one node of the given graph and apply modified BFS on it. (The modified BFS allows one child node to have multiple parents and hence o/p is a DAG instead of tree).
		Given graph
		<pre> graph LR A((A)) --> B((B)) A((A)) --> C((C)) B((B)) --> D((D)) B((B)) --> C((C)) D((D)) --> E((E)) D((D)) --> F((F)) C((C)) --> G((G)) F((F)) --> G((G)) </pre>

		Moderator	
		Re-Assessor	

Space for Marks	Question No.	START WRITING HERE
		<p>Consider a node (say E).</p> <p>Applying modified BFS on E, we get</p> <pre> graph TD E((E)) --- D((D)) E --- F((F)) D --- B((B)) D --- C((C)) F --- G((G)) B --- A((A)) B --- C G --- F </pre>

2) Assign values for each edge from bottom to top. A child having multiple parents gives $0.5(\frac{1}{2})$ to both parents or $(\frac{1}{3})$ to all 3 parents, and so on--.

Values for each edge in above case is:

Hence, with E as root node (i.e source), there are 3 shortest paths that travel from D to B.

Summing up the paths from all above graphs we get total. This total when divided by 2 gives edge betweenness as follows :-

Removing edge BD that has highest edge betweenness (12), we get 2 communities as shown

The above procedure is to be repeated separately for both the communities $\{A, B, C\}$ & $\{D, E, F, G\}$ to detect further communities.

2) Histogram:

A histogram is like a bar chart as it uses bars of varying height to represent data distribution. However, in a histogram, values are grouped into consecutive intervals called bins. Continuous values are grouped and displayed ~~as~~ in these bins whose size can be varied.

Ex: hist (airquality \$ Temp, main = "maximum Temperature (Daily)", xlab = "Temperature (Fahrenheit)", xlim = c(50, 125), col = "yellow", freq = TRUE)

Histogram are useful to verify an equal and symmetric distribution of data and to identify deviations from expected values.

3) Box Plots:

Statistical summary of the given data is presented graphically using a boxplot. A boxplot depicts information like the minimum and maximum data points, the median value, first and third quartiles, and inter-quartile range.

Ex: boxplot ("airquality" \$ Wind, main = "Wind speed")

xlab = "miles per hour", col = "orange",
border = "brown", horizontal = "T", RUE = ,
notch = "TRUE")

Box plot is useful to give a comprehensive
statistical description of the data and
identify the outlier points.

4) Scatter Plot:

A scatter plot is composed of many
plots on cartesian plane. Each point denotes
the value taken by two parameters and
helps us easily identify the relationship
between them.

Ex plot (airquality \$ozone, airquality \$Month,
main = "Scatterplot", xlab = "Ozone
concentration in parts per billion"
ylab = "Month of observation",
pch = 19)

Scatter plot is useful to show whether an
association exists between bivariate data
and to measure the strength and
direction of such a relationship.

* Other types include Heatmap(), 3D graphs
using rggp(), and shinyapp using
library (rsgui).
